

MOBILE DATA MANAGEMENT SYSTEM

ABSTRACT OF THE DISCLOSURE

A medical treatment system that treats patients by using a data management system is described. Using the data management system creates several advantages including allowing emergency medical personnel additional treatment time and hospitals additional preparation time. The mobile data management system includes an interface that transfers data associated with the patient from an input device. A control system analyzes the data and generates a report that identifies medically relevant data. The management system also includes a display for viewing either the data or the report. A communication system transfers the report to a remote location before the patient arrives. Alternatively, an emergency medical treatment system for use by medical personnel in treating a patient en route to a medical facility is also described. The emergency system also includes an interface, control system, display, and communication system.
